Sound may be an important addition to some websites: music and voice files, as well as a built-in player can help the visitors relax, catch the vibe and better interact with pages. Of course, audio should be used wisely: well-selected, comfortable in terms of volume and causing no interference with the contents of the site.

Until recently, developers could add sound files to web pages only via `<bgsound>` tag. It set the audio as the background sound and played it while the user is viewing the page, giving no ability to turn it off (not cool).

To solve this problem, a new tag `<audio>` was added to the fifth version of the HTML standard.

Let's look at how to add audio to a web page using the latest HTML5 features.

## §1. Syntax

The `<audio>` tag is used to embed audio content into web pages. When using this tag, HTML markup looks like this:

```
1 <audio src="media/example.mp3"></audio>
```

or like that, using a nested `<source>` tag and the same audio recording in different formats:

```
1 <audio>
2   <source src="media/example.mp3" type="audio/mpeg">
3   <source src="media/example.ogg" type="audio/ogg">
4 </audio>
```

The path to the file can be set both through the `src` attribute and the nested `<source>` tag. The latter option is used to add the same media content in different formats since at the moment there is no audio format that works in all browsers.

## §2. Attributes of tags

There are several attributes for the `<audio>` tag that control playback and audio settings on a web page. Consider some of the most commonly used ones:

- `src` indicates the path to the file that's played
- `controls` displays the audio player control interface (playback buttons, pause, volume)
- `autoplay` is responsible for automatic playback of the file immediately after the page is loaded
- `loop` cycles the audio file
- `muted` mutes the sound when playing an audio file

In one of the variants of adding audio to the web page you may have noticed the type attribute. With a `<source>` tag, you should always specify the `type` attribute. It allows the browser to determine the types of media files and play the desired one. Here is a table from which you can find out the media format you need:

File Format	Media Type
MP3	audio/mpeg
OGG	audio/ogg
WAV	audio/wav

[Feedback & Comments](#)

The `<audio>` tag can be seen on the web page only if the `controls` attribute is specified:

```
1 | <audio controls src="media/example.mp3"></audio>
```

Each browser displays this element in its own way:

Now you know how to add audio to your web pages, which might present your website to the viewers in a whole new light – or the whole new sound. Congratulations!
